

The program, if launched, is able to recognize only texts written in English and Italian.

In case you would like to train the program with other languages, you have to download new text files, save them in the **texts directory**, and use the appropriate methods.

The program can not recognize letters that are not in the English alphabet. For this reason it could encounter difficulties with languages like German.

In case the program makes inaccuracies, you can train it with new books written in the known languages.

The **Histogram** class is used only to make it easier to visualize a **linguistic model**. It is a class used mainly for testing. The program works independently from it. For these reasons the **print** method of the **Trainer** class has directly the **System.out.println()**.

You can use this program as a basis for a larger project.
